Kryvtsova M. V., Kostenko Ye. Ya. Dominant microbial associations of oral cavity periodontitis and features of their sensitivity to antibacterial drugs. **Studia Biologica**, 2020: 14(1); 51–62 • DOI: <https://doi.org/10.30970/sbi.1401.613>

Opportunistic microorganisms play a significant role in the development of inflammatory diseases, including generalized periodontitis. The growing tendency towards the formation of antibiotic resistant microorganisms causes the relevance of monitoring the microorganisms' sensitivity to antimicrobial drugs and the development of new approaches to the antimicrobial therapy. The purpose of this work was to determine the dominant microbial associations of the oral cavity in the conditions of generalized periodontitis, to study their sensitivity to antibiotics, antiseptics and phytopreparations. The microbial associations' study at generalized periodontitis was performed by bacteriological monitoring of the pathological material from the foci of the inflammatory process. Determination of the isolates' antibiotic susceptibility to antiseptics and phytopreparations was carried out by the disc diffusion method, in the agar. As test culture, the following bacteria and yeast from the American Type Culture Collection were used: *Candida albicans* ATCC 885-653; *Staphylococcus aureus* ATCC 25923; *Escherichia coli* ATCC 25922; *Enterococcus faecalis* ATCC 29212; *Streptococcus pyogenes* ATCC 19615; and *Pseudomonas aeruginosa* ATCC ATCC 27853. We also used clinical strains of bacteria and yeasts (*S. aureus*, *K. rhinoscleromatis*, *H. alvei*, *E. coli*, *S. pyogenes*, *S. pneumoniae*, *C. albicans*, *C. glabrata* isolated from the oral cavities of patients suffering from the inflammatory periodontium. We selected clinical strains with multiple resistance to antibiotics. The results of studies have shown that the opportunistic microorganisms dominated

in 100 % of cases within the oral cavity microbiota in patients with generalized periodontitis. The most pronounced clinical symptoms of the disease and recurrent inflammation were observed with the persistence of the *Staphylococcus* genus bacteria association with the *Enterobacteriaceae* family bacteria and *Pseudomonas* bacteria genera, microscopic *Candida* genus fungi in the oral cavity. It was found that the fluoroquinolones and cefoperazone/sulbactam were the most effective against the isolates. Among the commercial preparations, Sangviritrin showed the most expressive antimicrobial activity and its antibacterial effect was registered on the clinical isolates of *S. aureus*. It is worth noting that the Sangviritrin showed the antimicrobial effect against an extra antibiotic-resistant isolates resistant to all phytopreparations and disinfectants used in the test. A high antimicrobial activity of Decasanum and Sangviritrin against the multi-antibiotic resistant strains, most by against Gram-positive bacteria, was established. The established regularities determine the relevance of the antibiotic therapy taking into account the antibiotic susceptibility of the inflammatory process pathogens and the development of a comprehensive approach for correction of the opportunistic microbiota at generalized periodontitis.

Keywords: antibiotic resistant isolates, opportunistic microorganisms, antibacterial activity, oral cavity microbiota

INTRODUCTION

The inflammatory diseases of the periodontal tissues, including generalized parodontitis, are multifactorial diseases, in whose etiology, the microbial factor occupies the key position [2, 6, 13]. At the first stages of the periodontitis formation, significant disorders of the periodontal tissues local immunity and anaerobic Gram-negative *Actinobacillus actinomycetemcomitans*, *Porphyromonas gingivalis*, *Prevotella intermedia* and *Tannerella forsythensis* bacteria play an important role, being involved in the periodontal pockets formation, the connective tissue destruction, and the alveolar bone resorption. The inflammatory infiltrate formation is accompanied by a variety of immunopathologies.

Along with this, the cause of complications and recurrences of the inflammatory periodontal disease is the microbial cenosis restructuring and the opportunistic microorganisms domination within the microbial associations of the oral cavity. The colonization of the mucous membrane with transient and allochthonic microbiota representatives, frequently manifesting multiple resistance to antibiotics, leads to a permanent recurrence and chronic inflammatory process [4, 15]. Due to this particular reason, some authors consider periodontitis that is an opportunistic infection, accompanied by the presence of opportunistic and pathogenic bacteria in the oral cavity [7, 12, 13]. It is also established that bacteria causing inflammatory periodontal processes can be a separate risk factor for cardiovascular, cerebrovascular diseases and premature delivery [8, 11]. That is why, antibacterial drugs are widely used in treatment of the periodontal tissues [4, 13, 14].

At the same time, the ever-increasing trend towards the formation of the antibiotic resistance, especially among the representatives of the opportunistic microbiota, including that in the biofilm [8, 18], requires new approaches to both local and systemic treatment. Under such conditions, a permanent monitoring of the poly-antibiotic resistant

microorganisms circulation, the study of their sensitivity to antibacterial drugs, the development of new integrated approaches and means for the oral microbiocenosis correction in the inflammatory process is relevant.

The purpose of the present study was to determine the dominant microbial associations of the oral cavity at generalized periodontitis, to clarify their sensitivity to antibiotics, antiseptics and phytopreparations.

MATERIALS AND METHODS

The isolates that caused periodontal inflammatory processes were isolated on the basis of the Dental Polyclinic at Uzhhorod National University; the antimicrobial activity was studied at the Microbiology Laboratory at the Department of Genetics, Plant Physiology and Microbiology, Uzhhorod National University.

As the test culture, the following bacteria and fungi from the American Type Culture Collection were used: *Candida albicans* ATCC 885-653; *Staphylococcus aureus* ATCC 25923; *Escherichia coli* ATCC 25922; *Enterococcus faecalis* ATCC 29212; *Streptococcus pyogenes* ATCC 19615. We also used clinical strains of bacteria and fungi (*S. aureus*, *K. rhinoscleromatis*, *H. alvei*, *E. coli*, *S. pyogenes*, *S. pneumoniae*, *C. albicans*, *C. glabrata* isolated from the oral cavities of patients suffering from inflammatory periodontitis. We have selected clinical strains with multiple resistance to antibiotics.

The following domestically produced commercial phytopreparations were used in the study: Sangviritrin (DKP Pharmaceutical Factory LLC, Zhytomyr), Tinctura Salviae ("Vishpha", Lviv), Rotocanum (State Enterprise "Experimental Plant of Medicines IBONH NAS of Ukraine", Kyiv, Ukraine), Tinctura Eucalypti (Fitofarm JSC, Bakhmut), Chlorophyllipt (Arterium, Halychpharm JSC, Lviv), Tinctura Menthae (Viola Pharmaceutical Factory, Zaporizhia.), and Mint mouth rinse (Herbaria, Hungary).

The following disinfectants were used: Decasanum (Yuria-Pharm LTD, Kyiv, Ukraine), Dioxydine (Farmak JSC, Kyiv, Ukraine) Chlorhexidine (Monfarm JSC, Monastyryshche, Ukraine), Metronidazole (Yuria-Pharm Kyiv, LTD., Ukraine), Miramistin (PrAT "Darnitsa Farmaceutical Company", Kyiv, LTD., Ukraine).

We examined 180 patients diagnosed for generalized periodontitis; the control group composed of 50 persons without such diagnosis. The biological material was collected from the mucous membrane of the inflammatory site using a sterile transport system (a test tube with gel and an applicator for biological fluids produced by FLmedical (Italy). The material was plated according to Gold on nutrient media: Sabourund Dextrose Agar, HiCrome™ *Candida* Differential Agar (Himedia) for the cultivation of microscopic fungi, hemolytic microflora, namely, the *Streptococcus* and *Neisseria* genera bacteria on the blood agar, *Enterobacteriaceae* genera bacteria – on Endo and Ploskirev agar (Farmaktiv, Ukraine), the *Staphylococcus* genus bacteria – on Mannitol Salt Agar (Biolif-Italia), *Enterococci* were identified with Bile esculin agar (Biolif-Italia).

We identified the bacteria and fungi based on macromorphology, micromorphology, physiological and biochemical tests using ENTEROtest, STREPTO-test, STAPHYLO-test produced by Erba Lachema.

The antibiotic sensitivity of bacteria and microscopic fungi was identified by the disc diffusion method according to the accepted procedure (Order No. 167 of the MOH of Ukraine dated 05/04/2007; EUCAST (European Committee on Antimicrobial Susceptibility Testing).

The bacteria isolates were screened for a susceptibility to the following antibiotics: ampicillin (10 µg), amoxicillin-clavulanic acid (20/10 µg), cefazolin (30 µg), ceftriaxone (30 µg), imipenem (10 µg), meropenem (10 µg), cefuroxime (50 µg), cefoperazone/sulbactam (75 µg), ciprofloxacin (5 µg), levofloxacin (5 µg), gatifloxacin (5 µg), norfloxacin (10 µg), ofloxacin (1 µg), lomefloxacin (10 µg), tetracycline (30 µg), erythromycin (15 µg), azitromycin (15 µg), clarithromycin (15 µg). The fungi isolates were screened for susceptibility to the following antibiotics: (in 6 mm diameter wells) with nystatin (50 µg), itroconazole (10 µg), fluconazole (25 µg), ketoconazole (10 µg), voriconazole (1 µg), klotrimazole (10 µg), miconazole (50 µg).

The microorganisms' sensitivity to plant-based materials and disinfectants was determined by the standard agar diffusion test (with 8 mm diameter wells) [3]. The antibacterial properties was carried out according to the following criteria: absence of a growth retardation zone of 10 mm, indicating that the microorganisms are not sensitive to the sample inserted into the well; that of 10–15 mm indicates a weak sensitivity; 15–25 mm means sensitivity; more than 25 mm – high sensitivity.

The data obtained were expressed as mean \pm standard deviation (SD) of three measurements. The Tukey's test was applied for comparisons of mean values, differences were considered reliable at $p < 0.05$. Statistical analysis and comparisons among the means were carried out using Microsoft Excel 2013. The parameters calculated alongside with the basic variation were: average and standard deviation; minimum and maximum coefficients of variation; and the inhibition zones size frequency.

RESULTS AND DISCUSSION

The total of 389 opportunistic microorganisms strains were isolated from 180 patients with persistent inflammatory process at generalized periodontitis. The *Staphylococcus* genus bacteria were isolated from the inflammatory site in 73 % (131/180) cases and were represented by four species: *S. aureus*, *S. haemolyticus*, *S. saprophyticus*, *S. epidermidis*. In 53 patients *S. aureus* was isolated, 20 of them being methicillin-resistant. In 44 patients, *S. haemolyticus* was isolated.

The *Streptococcus* genus bacteria were isolated in 37.2 % (67/180) of the patients with generalized paradontitis belonging to the *S. pyogenes*, *S. agalactiae*, *S. viridans*, *S. mutans*, *S. pneumoniae* species. The *Enterococcus* genus bacteria were isolated in 30 % (54/180) cases. In 38.9 % (70/180) of the patients, the *Enterobacteriaceae* family bacteria were isolated whose species diversity was represented by the following species: *Escherichia coli*, *Enterobacter cloacae*, *Citrobacter freundii*, *Klebsiella rhinoskleromatis*, *Hafnia alvei*.

It was reported that in patients with the most acute symptoms of the disease, the following associations of microorganisms were isolated: *S. aureus* + *E. faecalis*; *S. epidermidis* + *E. cloacae*; *S. haemolyticus* + *E. cloacae*; *S. aureus* + *K. rhinoskleromatis*; *S. saprophyticus* + *C. glabrata* + *E. cloacae*; *S. saprophyticus* + *C. freundii*; *S. aureus* + *H. alvei* + *C. albicans*.

The total of 45 microscopic fungi strains of the *Candida* genus were isolated, 38 of them belonging to *C. albicans*, 5 strains – to *C. glabrata*, 2 – *C. cruzi*. In patients with generalized periodontitis, the following representatives of indigenous microbiota were isolated: nonpathogenic streptococci *S. sanguis*, *S. mitis*, *S. salivarius*. In 57 % cases the *Lactobacillus* genus bacteria were isolated.

By studying the microbiota of mouth cavity in control group patients, we ascertained presence of the nonpathogenic *Streptococcus* spp.; lactobacilli were identified in 91.5 % of the reviewed material and only in 57 % of patients suffering from the periodontitis. The microbiota of the healthy gum tissues was characterized by a low population level of microbial populations of opportunistic microorganisms (*S. saprophyticus*, *S. epidermidis*) – 22 %. However, at chronic generalized periodontitis, the opportunistic associations prevailed.

A high degree of antibiotic resistance in the microorganisms isolated from the inflammatory process foci with generalized periodontitis was shown – 48 % of isolates were resistant to at least 7 antibiotics. Thus, 3 isolates of *K. rhinoskleromatis* were resistant to 30 antibiotics. All the isolates were resistant to ampicillin, erythromycin, tetracycline.

The study results on the isolates' antibiotic susceptibility showed that 57.65 % of isolates were susceptible to amoxicillin/clavulanate, 5.3 % were moderately sensitive and 37.05 % were resistant.

Isolates in the amount of 85.29 % showed resistance to cephalosporins of the 1st generation. Sensitivity to cephalosporins of the second generation has been established: to ceftriaxone – 61.76 % and to cefuroxime – 55.29 % of cultures. It was shown that 97 % of isolates were susceptible to cefoperazone/sulbactam.

It was established that 73 % of all isolates were susceptible to fluoroquinolones, in particular to fluoroquinolones of the second generation: to ofloxacin – 41.76 % of isolates; to norfloxacin – 68.23 %; to lomefloxacin – 32.35 %; to ciprofloxacin – 68.82 %; to fluoroquinolones of the third generation: to levofloxacin – 75.29 %, and to the forth generation fluoroquinolones (gatifloxacin) – 87 %.

The opportunistic microorganisms were susceptible to the cabopenems: 80 % – to meropenem and 58.23 % – to imipenem.

Of the 170 isolates, 15.29 % were sensitive to azithromycin, 30 % were moderately susceptible and 55.29 % were resistant. 30 % of cultures were sensitive to the semi-synthetic clarithromycin macrolides.

The microscopic *Candida* genus fungi was resistant to fluconazole, 6 strains showed sensitivity to itraconazole, 10 – to clotrimazole.

The conducted studies have shown that Dexasan antiseptic exhibited a wide spectrum of antimicrobial activity (see Figure). In particular, the sensitivity of all bacteria involved in the experiment as clinical isolates and typical cultures has been established. The highest levels of antimicrobial activity were recorded for the *Staphylococcus* genus bacteria, including methicillin-resistant strains. However, the antimycotic action of Dexasan on *Candida* species in the drug dose selected by us was not detected.

High antibacterial effect was observed as a result of the Dioxydine action, but the parameters of growth retardation zones varied greatly from 30.33 ± 0.58 mm to the clinical strain of *S. aureus* to $17.33 \pm 0.33^\circ$ to *S. aureus* MRSA. High antibacterial activity of dioxydine on *S. pneumonia* has also been established. The bactericidal activity of the drug against *E. faecalis* and *K. rhinoscleromatis* was not detected. Moderate activity of the dioxydine against *E. coli* has been established.

The moderate sensitivity of the *Staphylococcus* genus bacteria to chlorhexidine is shown, but it is much lower than that of Dioxydine and Dexasane. Chlorhexidine did not affect methicillin-resistant *S. aureus*, and no antibacterial effect of chlorhexidine on the *Streptococcus* genus bacteria was detected.

Antimicrobial activity of antiseptics and antibacterial preparations toward typical and clinical isolates of microorganisms

Антимікробна активність антисептиків і антибактеріальних препаратів на типові та клінічні ізоляти мікроорганізмів

Sensitive to chlorhexidine were *E. faecalis* and *E. coli*, however, *K. rhinoscleromatis* was not susceptible to the above antiseptic. The antimycotic effect of the chlorhexidine is shown. *E. faecalis*, *S. pneumoniae*, *S. viridans* exhibited a moderate sensitivity to miramistin. Moderate antibiotic activity of metronidazole with *S. pyogenes* ATCC 19615 is shown.

The studies have shown a high level of the antimicrobial activity of the Sangviritrin drug, possessing a high antibacterial effect on Gram-positive microorganisms, a moderate effect on Gram-negative bacteria and a weak antimycotic activity (Table 1, Table 2). The Chlorophyllipt phytopreparation demonstrated high *in vitro* efficacy towards the *Staphylococcus* genus bacteria, more towards typical strains than to clinical ones, and to *E. faecalis*, weak and moderate activity towards *E. coli*.

The Eucalyptus tincture showed a high and moderate activity towards the isolates. No antimicrobial activity of the Mint rinse was detected, and low and moderate activity of the "Salvia" tincture towards the *Staphylococcus* and *Streptococcus* genera bacteria was observed. The Rotocanum drug produced a moderate and low antimicrobial effect on isolates involved in the experiment, except for *E. coli* and *S. aureus* (MRSA).

At chronic persistent inflammatory process, the opportunistic microorganisms dominate in the oral cavity of patients with generalized periodontitis.

The obtained results are consistent with the data of other researchers [8] who established the domination of the *Staphylococcus* genus bacteria in the microbiota of the oral cavity in patients with generalized periodontitis. The authors also identify the *S. aureus*, *S. epidermidis*, *Bacteroides* spp., *Actinomyces* spp., *Candida* spp., *Pseudomonas aeruginosa* and *Streptococcus* spp. microorganisms, as the most important agents

causing the development of generalized periodontitis and the role of the above microorganisms proteolytic enzymes, including collagenolytic enzymes, hyaluronidase, chondroitin sulfatase in the disintegration of collagen, the main protein of the periodontal tissue. The authors also report high sensitivity of the opportunistic microbiota to clindamycin and ofloxacin.

Other authors reported about the domination of the *Streptococcus* spp., *Staphylococcus* spp., *Kocuria* spp., *Enterobacter* spp. genera representatives and of the *Candida* spp. genus yeast-like fungi in the periimplant region of patients with mucositis. All isolates demonstrated sensitivity to fluoroquinolones and were resistant to penicillins, macrolides, lincosamines, that coincided with our results [5].

Colonization of the oral cavity with pathogenic bacteria can be an antecedent and, in its turn, can lead to other diseases [1]. Diseases of the periodontal tissues contribute to the oropharyngeal colonization by potential respiratory pathogens, including *Enterobacteriaceae* (*K. pneumoniae*, *E. coli*, *Enterobacter* sp., *P. aeruginosa*, and *S. aureus*).

The persistence of opportunistic microorganisms in the oral cavity creates preconditions for the development of systemic diseases, especially, this correlation is established in the elderly persons [1, 2].

The domination of opportunistic microorganisms in the oral cavity in conditions of generalized periodontitis causes the need for antibacterial therapy. The literature data report that according to the dental practitioners' survey, amoxicillin (73.58 %) is the most frequently prescribed as an antibiotic systemic treatment, 36.47 % of dentists recommend lincomycin to patients, and fluoroquinolone preparations (ciprofloxacin) are prescribed by 30.18 % of dental practitioners, doxycycline – by 17.61 %, clarithromycin – by 5.03 % [1]. Our studies showed high sensitivity of the opportunistic microorganisms, isolated from the inflammatory foci, to fluoroquinolones, however, their high resistance to penicillins, macrolides, lincomycin, doxycycline was established.

It is shown that most microorganisms causing complications of dental implantation are resistant to penicillins, macrolides, lincosamines [2]. A significant increase in the level of antibiotic resistant strains of microorganisms in conditions of periodontal inflammatory diseases, may be due to the presence of bacteria in the composition of biofilm. It has been proved that the resistance of bacteria to antibiotics within the biofilm is several orders greater [4, 6, 11, 17].

At the same time, the auxiliary or alternative means of the opportunistic microbiota correction is the use of local antiseptics and phytopreparations to potentiate the action of antibiotics, and in benign cases, an alternative to their application [5, 8]. We have established low efficacy of the antimycotic drugs, particularly their local effects. Meanwhile, in our previous studies, high activity of essential oils [9, 10, 16] and phytopreparations to isolates of opportunistic infections pathogens, including microscopic fungi of the *Candida* genus was established.

CONCLUSION

At generalized periodontitis, the domination of conditionally pathogenic microorganism associations in the microbiote of the oral cavity was observed. Association of the bacteria of *Staphylococcus* genus and *Enterobacteriaceae* family accompanied the most complex recurrent inflammatory processes. High percentage of the antibiotic resistant isolates is shown.

It was found that the most effective against the isolates were fluoroquinolones and cefoperazone/sulbactam. Among antiseptics, Decasanum demonstrated a wide range of the antibacterial activity. The high antimicrobial effect was demonstrated by Sangviritrin.

The application of a comprehensive, differential approach to the correction of microbiota in the oral cavity at generalized periodontitis is grounded. Taking into account the dominant associations and their sensitivity to antibacterial drugs, including phyto-preparations, which, in addition to antimicrobial activity, do not violate the composition of the indigenous microbiota.

Умовно-патогенні мікроорганізми відіграють значну роль у розвитку запальних захворювань, зокрема, генералізованого пародонтиту. Персистенція представників алохтонної мікробіоти у ротовій порожнині хворих із генералізованим пародонтитом

створює передумови для ускладнення основного захворювання та потребує застосування антибактеріальних препаратів. Нераціональне використання антимікробних препаратів призводить до поширення резистентних мікроорганізмів. Саме зростаюча тенденція до формування антибіотикорезистентності визначає актуальність моніторингу чутливості мікроорганізмів до антимікробних препаратів і розробки нових підходів до антимікробної терапії. Важливим фактором успішного застосування препаратів з антимікробною активністю є постійний моніторинг чутливості мікроорганізмів до антибіотиків і антисептиків, які використовуються у стоматології. Крім того, особливу увагу привертають місцеві антисептики, які застосовувались у вигляді аплікацій, пародонтальних пов'язок, іригацій тощо. Метою роботи було визначити домінуючі мікробні асоціації ротової порожнини в умовах генералізованого пародонтиту, дослідити їхню чутливість до антибіотиків, антисептиків і фітопрепаратів. Вивчення мікробних асоціацій в умовах генералізованого пародонтиту проводили способом бактеріологічного дослідження патологічного матеріалу з вогнища запального процесу. Забір біологічного матеріалу зі слизової оболонки осередку запального процесу проводили за допомогою стерильної транспортної системи (пробірка з гелем і аплікатором для біологічних рідин виробництва FLmedical) (Italy). Матеріал висівали на диференційно діагностичні поживні середовища. Визначення антибіотикочутливості ізолятів проводили дискодифузійним методом, до антисептиків і фітопрепаратів – методом дифузії в агар. Дослідженням встановлено, що умовно-патогенні мікроорганізми у 100 % випадків домінували у складі мікробіоти ротової порожнини хворих на генералізований пародонтит. Найчіткіші клінічні симптоми захворювання і рецидивування запального процесу спостерігали у разі персистенції в ротовій порожнині асоціації бактерій роду *Staphylococcus* із бактеріями родини *Enterobacteriaceae* роду *Pseudomonas*, мікроскопічними грибами роду *Candida*. Персистенція умовно патогенних бактерій у ротовій порожнині хворих із генералізованим пародонтитом створює передумови для ускладнення основного захворювання та потребує застосування антибактеріальних препаратів. З'ясовано високий ступінь антибіотикорезистентності мікроорганізмів, ізольованих із осередків запального процесу в разі генералізованого пародонтиту, зокрема, 48 % ізолятів були стійкими як мінімум до 7 антибіотиків. Умовно-патогенні мікроорганізми були чутливими до кабопенемів: 80 % ізолятів до меропенему та 58,23 % іміпенему. Встановлено високий рівень стійкості до азитроміцину: зі 180 ізолятів 15,29 % були чутливими до азитроміцину, 30 % помірно чутливими та 55,29 % резистентними. Виявлено, що найефективнішими щодо ізолятів були фторхінолони і цефоперазон/сульбактам. З антисептиків Декасан виявляв широкий спектр антибактеріальної активності. Зокрема, встановлено чутливість усіх взятих в експеримент бактерій як клінічних ізолятів, так і типових культур. Найвищий рівень антимікробної активності реєстрували щодо бактерій роду *Staphylococcus*, зокрема, метицилін резистентний штам. Декасан виявляв активність до клінічних поліантибіотикорезистентних штамів *Klebsiella* spp. Проте антимікотичної дії Декасану на гриби роду *Candida* в обраній нами дозі препарату не виявлено. З'ясовано помірну чутливість бактерій роду *Staphylococcus* до хлоргексидину, проте значно нижчу, ніж Діоксидину та Декасану. Хлоргексидин не впливав на метицилінрезистентний *S. aureus*. Не виявлено антибактеріальної дії хлоргексидину щодо бактерій роду *Streptococcus*, встановлено також його антимікозний ефект. До Міра-

містину виявляли помірну чутливість *Enterococcus faecalis*, *Streptococcus pneumoniae*, *Streptococcus viridans*. Дослідженням виявлено високий рівень антимікробної активності препарату Сангвіритрин, який мав значний антибактеріальний ефект на грампозитивні мікроорганізми, помірну дію на грамнегативні бактерії та слабку антимікозну активність. Фіторепарат Хлорофіліпт показав високу *in vitro* ефективність на бактерії роду *Staphylococcus*, більшою мірою на типові штами, ніж на клінічні; слабку та помірну активність щодо *E. coli*. Препарат Ротокан виявляв помірну та низьку антимікробну дію на ізоляти, взяті в експеримент, і не впливав на *E. coli* та *S. aureus* (MRSA). Встановлені закономірності визначають актуальність проведення антибактеріальної терапії з урахуванням антибіотикочутливості збудників запального процесу і розробки комплексного підходу до корекції умовно-патогенної мікробіоти в умовах генералізованого пародонтиту.

Ключові слова: антибіотикорезистентні ізоляти, опортуністичні мікроорганізми, антибактеріальна активність, мікробіота ротової порожнини
