ABSTRACT. We present the results of the radial velocity $(R V)$ measurements of metallic lines as well as $\mathrm{H}_{\alpha}\left(\mathrm{H}_{\beta}\right)$ obtained in 55 high-resolution spectra of the Cepheid $\alpha$ UMi (Polaris Aa) in 1994-2010. While the $R V$ amplitudes of these lines are roughly equal, their mean $R V$ begin to differ essentially with growth of the Polaris Aa pulsational activity. This difference is accompanied by the $\mathrm{H}_{\alpha}$ core asymmetries on the red side mainly (so-called knifelike profiles) and reaches the value of $8-12 \mathrm{~km} / \mathrm{s}$ in 2003 with subsequent decrease to $1.5-2 \mathrm{~km} / \mathrm{s}$. We interpret so unusual behaviour of the $\mathrm{H}_{\alpha}$ line core as dynamical changes in the envelope around Polaris Aa.
Key words: - Stars: Cepheids - Stars: radial velocities - Stars: $\mathrm{H}_{\alpha}$ absorption line - Stars: envelopes Stars: individual - $\alpha$ UMi (Polaris A)

## 1. Introduction

Detecting the extended envelope around the Cepheid Polaris (hereafter Polaris Aa) using a near-infrared interferometer (Mérand et al. 2006) suggested an idea to check its presence spectroscopically. Usenko et al. (2013, 2014ab), Usenko and Klochkova (2015) revealed that the $\mathrm{H}_{\alpha}$ absorption line could be used as an indicator of the envelope presence not only in longperiod Cepheids but also in short-period ones. As a rule, Cepheids with pulsational periods longer than $7-$ $10^{d}$ demonstrate a pronounced appearance of the secondary variable absorption in the $\mathrm{H}_{\alpha}$ cores, thereas short-period ones be noted by more smoothed, so called knifelike form. Besides, a slight change in the $R V$ of the $\mathrm{H}_{\alpha}$ core with pulsational phase compared to that determined from the metal lines is another indicator of the envelope presence in Cepheids.

Hence the main goal of this work is to measure the $R V$ s of Polaris Aa in different pulsational phases using
the metal lines and $\mathrm{H}_{\alpha}$ (in some cases $\mathrm{H}_{\beta}$ ) line cores and to estimate visually the form of the latter ones.

## 2. Observations

Observations of Polaris Aa have been obtained using:

1. 1 m telescope of the Ritter Observatory, University of Toledo (Toledo, OH, USA) - fiberfed echelle spectrograph $1150 \times 1150$ pixel CCD ( $\lambda \lambda 5800-$ $6800 \AA$ ).
2. 2.1 m Otto Struve telescope of the McDonald Observatory (Texas, USA) - SANDIFORD spectrograph (McCarthy et al. 1993) $1200 \times 400$ pixel CCD ( $\lambda \lambda$ 5500-7000 $\AA$ ).
3. 6 m telescope BTA - SAO RAS (Russia) - LYNX (Panchuk et al. 1993), PFES (Panchuk et al. 1997), NES (Panchuk et al. 2006) spectrometers ( $\lambda \lambda$ 4470-7100 $\AA$.)

The data reduction was made using IRAF and MIDAS software packages, all measurements of the $R V$ were done using the DECH20 software (Galazutdinov 1992). In Table 1 we present these $R V$ data from the spectra obtained in 2005-2010. This table contains the measurements determined from the metal lines, $\mathrm{H}_{\alpha}$ and $\mathrm{H}_{\beta}$, respectively.

## 2. Radial velocity measurement analysis and the $H_{\alpha}$ line cores behaviour

As seen in Table 1 and Fig. 1, originally the difference between the measurements obtained from metal lines and $\mathrm{H}_{\alpha}$ (and one $\mathrm{H}_{\beta}$ ) for each spectrum does not exceed $1.5 \mathrm{~km} / \mathrm{s}$ in 1994. As seen from Fig. 2, the $\mathrm{H}_{\alpha}$ core does not demonstrate any visible asymmetries.

Figure 1: Radial velocity estimates of Polaris Aa during 1994-2010. Six-point stars, - estimates from metal lines, open five-point stars, - from $\mathrm{H}_{\alpha}$ line, open circles, - from $\mathrm{H}_{\alpha}$ line. A square polynomial approximation is drawn for the metal lines.

Figure 2: $\mathrm{H}_{\alpha}$ line core profiles of Polaris Aa during 1994-1999.

Figure 3: $\mathrm{H}_{\alpha}$ line core profiles of Polaris Aa during 2003

Since 1999 (HJD 2451240-2451361), this difference begins to increase (Fig. 1) and a slight asymmetry on the red side of the $\mathrm{H}_{\alpha}$ core are visible (Fig. 2). Two years later this difference becomes larger (from $1 \mathrm{~km} / \mathrm{s}$ to $2 \mathrm{~km} / \mathrm{s}$ ), and the asymmetries on the red side of

Figure 4: $\mathrm{H}_{\alpha}$ line core profiles of Polaris Aa during 2004

Figure 5: $\mathrm{H}_{\alpha}$ line core profiles of Polaris Aa during 2005-2006
the core get quite visible (Fig. 3) during two years (2001-2002).

During 2003 we can see the most interesting event when the difference between the measurements reaches $8-12 \mathrm{~km} / \mathrm{s}$ (see Table 1 and Fig. 1) and the $\mathrm{H}_{\alpha}$ core

Figure 6: $\mathrm{H}_{\alpha}$ line core profiles of Polaris Aa during 2008-2010
shows asymmetries on the red side as well as on the blue side (see Fig. 4).

Since 2004 this difference decreases to $2-2.5 \mathrm{~km} / \mathrm{s}$ (HJD 2453015-2453367), and the $\mathrm{H}_{\alpha}$ core exhibits asymmetries on the red side only (see Fig. 1 and 5).

During 2005-2006 (HJD 245689-2454073) the difference is less than $1 \mathrm{~km} / \mathrm{s}$ and the asymmetries are less visible (Fig. 6). The same one can see in other results obtained during 2008-2010 (HJD 2454077-2454934) (Fig. 7). It should be noted that the differences between the $\mathrm{H}_{\alpha}$ and $\mathrm{H}_{\beta}$ measurements are negligible.

## 3. Conclusions

We can summarize the results of our investigations as follows.

1. As seen from the results of Table 1 and Fig.1, amplitudes of the $R V$ curve from $\mathrm{H}_{\alpha}$ and $\mathrm{H}_{\beta}$ are very small and close to those determined from the metallic lines.
2. First $\mathrm{H}_{\alpha}$ line core asymmetries on the red side arise with an increase of the $R V$ curve amplitude after the historical minimum of the Polaris Aa pulsational activity in the beginning of the 1990s.
3. During 2003 the difference between the $R V$ estimates obtained from metal lines and the $\mathrm{H}_{\alpha}$ core reaches $8-12 \mathrm{~km} / \mathrm{s}$. This event is accompanied by
the pronounced asymmetries of the $\mathrm{H}_{\alpha}$ core on the red side as well as on the blue side.
4. Since 2004, the $\mathrm{H}_{\alpha}$ core asymmetries are observed on the red side only and nearly disappear after 2005, when $R V$ amplitude grows to the new minimum.
5. $\mathrm{H}_{\alpha}$ core asymmetries (so-called knifelike profile) in the Polaris Aa atmosphere show that this absorption line could be an indicator of the envelope presence in yellow pulsating supergiants with short periods and small amplitudes.
6. So unusual behaviour of the $\mathrm{H}_{\alpha}$ core during 2003 could be explained by dynamical changes in the envelope around of Polaris Aa.
