## VERIFICATION OF RESTRICTED EA-EQUIVALENCE FOR VECTORIAL BOOLEAN FUNCTIONS

We present algorithms for solving the restricted extended affine equivalence (REA-equivalence) problem for any m-dimensional vectorial Boolean functions in $n$ variables. The best of them has complexity $\mathrm{O}\left(2^{2 \mathrm{n}+1}\right)$ for REAequivalence $\mathrm{F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}\left(\mathrm{x} \oplus \mathrm{V}_{2}\right) \oplus \mathrm{M}_{3} \cdot \mathrm{x} \oplus \mathrm{V}_{1}$. The algorithms are compared with previous effective algorithms for solving the linear and the affine equivalence problem for permutations by Biryukov et. al.

Keywords: EA-equivalence, matrix representation, S-box, vectorial Boolean function.

## Introduction

Vectorial Boolean functions play very important role in ensuring high-level security for modern ciphers. They are used in cryptography as nonlinear combining or filtering functions in the pseudo-random generators (stream ciphers) and as substitution boxes (S-boxes) providing confusion in block ciphers. Up to date an important question of generation of vectorial Boolean functions with optimal characteristics to prevent all known types of attacks remains open. Sometimes equivalence (i.e. EA or CCZ) is used for achieving necessary properties without losing other ones (e.g. $\delta$-uniformity, nonlinearity) [1, 2].

However, very often, inverse problem occurs: it is needed to check several functions for equivalence. For instance, when finding a new vectorial Boolean function it is necessary to verify whether it is equivalent to already known ones as it happens in some of block ciphers, where several substitutions are used [3-5].

The complexity of exhaustive search for checking extended affine (EA) equivalence of functions from $F_{2}^{\mathrm{n}}=\mathrm{GF}\left(2^{\mathrm{n}}\right)$ to itself equals $\mathrm{O}\left(\mathrm{n}^{3 \mathrm{n}^{2}+2 \mathrm{n}}\right)$. When $\mathrm{n}=6$ the complexity is already $2^{120}$ that makes it impossible to perform exhaustive computing.

In the paper [1] Alex Biryukov et al. have shown that in case when given functions are permutations of $F_{2}^{\mathrm{n}}$, the complexity of determining restricted extended affine equivalence (REA) equivalence equals $\mathrm{O}\left(\mathrm{n}^{2} \cdot 2^{\mathrm{n}}\right)$ for the case of linear equivalence and $\mathrm{O}\left(\mathrm{n} \cdot 2^{2 \mathrm{n}}\right)$ for affine equivalence. In this paper we consider more general cases of REA-equivalence for functions from $F_{2}^{\mathrm{n}}$ to $F_{2}^{\mathrm{m}}$ and specify results, when time complexity can be reduced to polynomial. The complexities of our algorithms and the best previous known ones are given in Table 1.

Table 1
Complexities for solving REA-equivalence problem

| Restricted EA-equivalence | Complexity | m | $\mathrm{G}(\mathrm{x})$ | Source |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}\left(\mathrm{M}_{2} \cdot \mathrm{x}\right)$ | $\mathrm{O}\left(\mathrm{n}^{2} \cdot 2^{\mathrm{n}}\right)$ | $\mathrm{m}=\mathrm{n}$ | Permutation | $[1]$ |
| $\mathrm{F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}\left(\mathrm{M}_{2} \cdot \mathrm{x} \oplus \mathrm{V}_{2}\right) \oplus \mathrm{V}_{1}$ | $\mathrm{O}\left(\mathrm{n} \cdot 2^{2 \mathrm{n}}\right)$ | $\mathrm{m}=\mathrm{n}$ | Permutation | $[1]$ |
| $\mathrm{F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}\left(\mathrm{x} \oplus \mathrm{V}_{2}\right) \oplus \mathrm{V}_{1}$ | $\mathrm{O}\left(2^{2 \mathrm{n}+1}\right)$ | $\mathrm{m} \geq 1$ | $\dagger$ | Sec. 3 |
| $\mathrm{~F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}\left(\mathrm{x} \oplus \mathrm{V}_{2}\right) \oplus \mathrm{V}_{1}$ | $\mathrm{O}\left(\mathrm{m} \cdot 2^{3 \mathrm{n}}\right)$ | $\mathrm{m} \geq 1$ | Arbitrary | Sec. 3 |
| $\mathrm{~F}(\mathrm{x})=\mathrm{G}\left(\mathrm{M}_{2} \cdot \mathrm{x} \oplus \mathrm{V}_{2}\right) \oplus \mathrm{V}_{1}$ | $\mathrm{O}\left(\mathrm{n}^{2} \cdot 2^{\mathrm{m}}\right)$ | $\mathrm{m} \geq 1$ | Permutation | Sec. 3 |
| $\mathrm{~F}(\mathrm{x})=\mathrm{G}\left(\mathrm{x} \oplus \mathrm{V}_{2}\right) \oplus \mathrm{M}_{3} \cdot \mathrm{x} \oplus \mathrm{V}_{1}$ | $\mathrm{O}\left(\mathrm{n} \cdot 2^{\mathrm{n}}\right)$ | $\mathrm{m} \geq 1$ | Arbitrary | Sec. 3 |
| $\mathrm{~F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}\left(\mathrm{x} \oplus \mathrm{V}_{2}\right) \oplus \mathrm{M}_{3} \cdot \mathrm{x} \oplus \mathrm{V}_{1}$ | $\mathrm{O}\left(2^{2 \mathrm{n}+1}\right)$ | $\mathrm{m} \geq 1$ | $\ddagger$ | Sec. 3 |
| $\mathrm{~F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}\left(\mathrm{x} \oplus \mathrm{V}_{2}\right) \oplus \mathrm{M}_{3} \cdot \mathrm{x} \oplus \mathrm{V}_{1}$ | $\mathrm{O}\left(\mathrm{m} \cdot 2^{3 n}\right)$ | $\mathrm{m} \geq 1$ | Arbitrary | Sec. 3 |

$\dagger-\mathrm{G}$ is under condition $\left\{2^{\mathrm{i}} \mid 0 \leq \mathrm{i} \leq \mathrm{m}-1\right\} \subset \mathrm{img}\left(\mathrm{G}^{\prime}\right)$ where $\mathrm{G}^{\prime}(\mathrm{x})=\mathrm{G}(\mathrm{x})+\mathrm{G}(0)$.
$\ddagger-\mathrm{G}$ is under condition $\left\{2^{\mathrm{i}} \mid 0 \leq \mathrm{i} \leq \mathrm{m}-1\right\} \subset \operatorname{img}\left(\mathrm{G}^{\prime}\right)$ where $\mathrm{G}^{\prime}(\mathrm{x})$ is defined as (5).

## Preliminaries

For any positive integers n and m , a function F from $F_{2}^{\mathrm{n}}$ to $F_{2}^{\mathrm{m}}$ is called differentially $\delta$-uniform if for every $\mathrm{a} \in \mathcal{F}_{2}^{\mathrm{n}} \backslash\{0\}$ and every $\mathrm{b} \in \mathcal{F}_{2}^{\mathrm{m}}$, the equation $\mathrm{F}(\mathrm{x})+\mathrm{F}(\mathrm{x}+\mathrm{a})=\mathrm{b}$ admits at most $\delta$ solutions [6]. Vectorial Boolean functions used as S-boxes in block ciphers must have low differential uniformity to allow high resistance to differential cryptanalysis [7]. In the important case when $\mathrm{m}=\mathrm{n}$, differentially 2 -uniform functions, called almost perfect nonlinear (APN), are optimal (since for any function $\delta \geq 2$ ).

The notion of APN function is closely connected to the notion of almost bent ( AB ) function [8], which can be described in terms of the Walsh transform of a function $\mathrm{F}: \mathcal{F}_{2}^{\mathrm{n}} \mapsto \mathcal{F}_{2}^{\mathrm{m}}$ :

$$
\lambda(u, v)=\sum_{x \in F_{2}^{\mathrm{n}}}(-1)^{v \cdot F(x)+u \cdot x}
$$

where "." denotes inner products in $F_{2}^{\mathrm{n}}$ and $\mathcal{F}_{2}^{\mathrm{m}}$, respectively. The set $\left\{\lambda(u, v) \mid(u, v) \in F_{2}^{n} \times F_{2}^{m}, v \neq 0\right\}$ is called the Walsh spectrum of $F$ and the set $\left\{|\lambda(u, v)| \mid(u, v) \in F_{2}^{n} \times F_{2}^{\mathrm{m}}, v \neq 0\right\}$ the extended Walsh spectrum of $F$. If $m=n$ and the Walsh spectrum of $F$ equals $\left\{0, \pm 2^{\frac{n+1}{2}}\right\}$ then the function $F$ is called $A B$ [8]. AB functions exist for n odd only and oppose an optimum resistance to linear cryptanalysis [9]. Every AB function is APN but the converse is not true in general (see [10] for comprehensive survey on APN and $A B$ functions).

The natural way of representing F as a function from $F_{2}^{\mathrm{n}}$ to $\mathscr{F}_{2}^{\mathrm{m}}$ is by its algebraic normal form (ANF):

$$
\sum_{I \subseteq\{1, \ldots, n\}} a_{I}\left(\prod_{i \in I} x_{i}\right), \quad a_{I} \in \mathcal{F}_{2}^{m}
$$

the sum being calculated in $F_{2}^{\mathrm{m}}$. The algebraic degree $\operatorname{deg}(\mathrm{F})$ of F is the degree of its ANF. F is called affine if it has algebraic degree at most 1 and it is called linear if it is affine and $F(0)=0$.

Any affine function $\quad \mathrm{A}: F_{2}^{\mathrm{n}} \mapsto F_{2}^{\mathrm{m}} \quad$ can $\quad$ be represented in matrix form

$$
\begin{equation*}
\mathrm{A}(\mathrm{x})=\mathrm{M} \cdot \mathrm{x} \oplus \mathrm{C} \tag{1}
\end{equation*}
$$

where $M$ is an $n \times m$ matrix and $C \in F_{2}^{m}$. All operations are performed in $\mathcal{F}_{2}$, thus (1) can be rewritten as
$\left(\begin{array}{c}a_{0} \\ a_{1} \\ \cdots \\ a_{m-1}\end{array}\right)_{x}=\left(\begin{array}{ccc}k_{0,0} & \cdots & k_{0, n-1} \\ k_{1,0} & \cdots & k_{1, n-1} \\ \vdots & \ddots & \vdots \\ k_{m-1,0} & \cdots & k_{m-1, n-1}\end{array}\right) \cdot\left(\begin{array}{c}x_{0} \\ x_{1} \\ \cdots \\ x_{n-1}\end{array}\right) \oplus\left(\begin{array}{c}c_{0} \\ c_{1} \\ \cdots \\ c_{m-1}\end{array}\right)$
with $\mathrm{a}_{\mathrm{i}}, \mathrm{x}_{\mathrm{i}}, \mathrm{c}_{\mathrm{i}}, \mathrm{k}_{\mathrm{j}, \mathrm{s}} \in \mathcal{F}_{2}^{\mathrm{m}}$.
Two functions $\mathrm{F}, \mathrm{G}: \mathscr{F}_{2}^{\mathrm{n}} \mapsto \mathscr{F}_{2}^{\mathrm{m}}$ are called extended affine equivalent (EA-equivalent) if there exist an affine permutation $\mathrm{A}_{1}$ of $\mathcal{F}_{2}^{\mathrm{m}}$, an affine permutation $\mathrm{A}_{2}$ of $F_{2}^{\mathrm{n}}$ and a linear function $\mathrm{L}_{3}$ from $F_{2}^{\mathrm{n}}$ to $F_{2}^{\mathrm{m}}$ such that

$$
\mathrm{F}(\mathrm{x})=\mathrm{A}_{1} \circ \mathrm{G} \circ \mathrm{~A}_{2}(\mathrm{x})+\mathrm{L}_{3}(\mathrm{x}) .
$$

Clearly $A_{1}$ and $A_{2}$ can be presented as $A_{1}(x)=L_{1}(x)+c_{1}$ and $A_{2}(x)=L_{2}(x)+c_{2}$ for some linear permutations $L_{1}$ and $L_{2}$ and some $c_{1} \in F_{2}^{m}$, $\mathrm{c}_{2} \in \mathcal{F}_{2}^{\mathrm{n}}$.

Definition 1. Functions $F$ and $G$ are called restricted EA-equivalent (REA-equivalent) if some elements of the set $\left\{L_{1}(x), L_{2}(x), L_{3}(x), c_{1}, c_{2}\right\}$ are in $\{0, x\}$.

There are two special cases

- linear equivalence when $\left\{\mathrm{L}_{3}(\mathrm{x}), \mathrm{c}_{1}, \mathrm{c}_{2}\right\}=\{0,0,0\} ;$
- affine equivalence when $L_{3}(x)=0$.

In matrix form EA-equivalence is represented as follows

$$
\mathrm{F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}\left(\mathrm{M}_{2} \cdot \mathrm{x} \oplus \mathrm{~V}_{2}\right) \oplus \mathrm{M}_{3} \cdot \mathrm{x} \oplus \mathrm{~V}_{1}
$$

where elements of $\left\{\mathrm{M}_{1}, \mathrm{M}_{2}, \mathrm{M}_{3}, \mathrm{~V}_{1}, \mathrm{~V}_{2}\right\}$ have dimensions $\{\mathrm{m} \times \mathrm{m}, \mathrm{n} \times \mathrm{n}, \mathrm{m} \times \mathrm{n}, \mathrm{m}, \mathrm{n}\}$.

We say that functions F and $\mathrm{F}^{\prime}$ from $F_{2}^{\mathrm{n}}$ to $F_{2}^{\mathrm{m}}$ are Carlet Charpin Zinoviev (CCZ) equivalent if there exists an affine permutation $\mathcal{L}$ of $\mathcal{F}_{2}^{\mathrm{n}} \times \mathcal{F}_{2}^{\mathrm{m}}$ such that $\mathrm{G}_{\mathrm{F}}=\mathcal{L}\left(\mathrm{G}_{\mathrm{F}^{\prime}}\right)$, where $\mathrm{G}_{\mathrm{H}}=\left\{(\mathrm{x}, \mathrm{H}(\mathrm{x})) \mid \mathrm{x} \in \mathcal{F}_{2}^{\mathrm{n}}\right\}$, $\mathrm{H} \in\left\{\mathrm{F}, \mathrm{F}^{\prime}\right\}$. CCZ-equivalence is the most general known equivalence of functions for which differential uniformity and extended Walsh spectrum are invariants. In particular every function CCZ-equivalent to an APN (respectively, AB ) function is also APN (respectively, AB ). EA-equivalence is a specific case of CCZequivalence [11]. The algebraic degree of a function is invariant under EA-equivalence but, in general, it is not preserved by CCZ-equivalence.

## Verification of Restricted EA-equivalence

Special types of REA-equivalence, which are considered in this paper, are shown in Table 2.

Hereinafter assume that obtaining the value $\mathrm{F}(\mathrm{x})$ for any x takes one step. Pre-computed values of function $\mathrm{F}(\mathrm{x}), \mathrm{F}^{-1}(\mathrm{x})$ and corresponding substitutions are used as input for the algorithms.

## Table 2

Special types of REA-equivalence

| REA-equivalence | Type |
| :---: | :---: |
| $\mathrm{F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}(\mathrm{x}) \oplus \mathrm{V}_{1}$ | I |
| $\mathrm{F}(\mathrm{x})=\mathrm{G}\left(\mathrm{M}_{2} \cdot \mathrm{x} \oplus \mathrm{V}_{2}\right)$ | II |
| $\mathrm{F}(\mathrm{x})=\mathrm{G}(\mathrm{x}) \oplus \mathrm{M}_{3} \cdot \mathrm{x} \oplus \mathrm{V}_{1}$ | III |
| $\mathrm{F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}(\mathrm{x}) \oplus \mathrm{M}_{3} \cdot \mathrm{x} \oplus \mathrm{V}_{1}$ | IV |

Thereafter, complexity of representing functions in needed form is not taken into account, as well as memory needed for data storage. These assumptions are introduced to be able to compare complexities of algorithms of the present paper with those of [1] where the same assumptions were made.

There are $2^{\mathrm{n} \cdot \mathrm{m}}$ choices of linear mappings. The complexity of obtaining the $m \times n$ matrix $M$ satisfying the equation

$$
\mathrm{F}(\mathrm{x})=\mathrm{M} \cdot \mathrm{G}(\mathrm{x})
$$

using exhaustive search method is $\mathrm{O}\left(2^{\mathrm{n}} \cdot 2^{\mathrm{m} \cdot \mathrm{n}}\right)$, where $\mathrm{O}\left(2^{\mathrm{m} \cdot \mathrm{n}}\right)$ and $\mathrm{O}\left(2^{\mathrm{n}}\right)$ are the complexities of checking all matrices for all possible $\mathrm{x} \in \mathcal{F}_{2}^{\mathrm{n}}$. Another natural method is based on system of equations. The complexity in this case depends only on the largest of the parameters $n$ and $m$. Indeed, for square matrices we can benefit from the asymptotically faster Williams method based on system of equations with complexity $\mathrm{O}\left(\mathrm{n}^{2.3727}\right)$ [12]. Besides, for $\mathrm{n} \leq 64$ we can use 64-bit processor instructions to bring the complexity to $\mathrm{O}\left(\mathrm{n}^{2}\right)$ because of two rows (columns) can be added in 1 step [13]. Since any system of $m$ equations with $n$ variables can be considered as a system of $k$ equations with $k$ variables where $k=\max \{n, m\}$ then the complexity of solving such system is

$$
\begin{equation*}
\mu=\mathrm{O}\left(\mathrm{k}^{2}\right) \tag{2}
\end{equation*}
$$

which gives the complexity of finding $M$ by this method.

Proposition 1. Any linear function $L: F_{2}^{\mathrm{n}} \mapsto \mathscr{F}_{2}^{\mathrm{m}}$ can be converted to a matrix with the complexity $\mathrm{O}(\mathrm{n})$.

Proof. We need to find an $m \times n$ matrix $M$ satisfying $L(x)=M \cdot x$. Suppose

$$
\begin{aligned}
\operatorname{rows}_{\mathrm{M}}(\mathrm{i}) & =\left(\mathrm{m}_{\mathrm{ij}}\right), \forall \mathrm{j} \in\{0,1, \ldots, \mathrm{n}-1\}, \\
\operatorname{cols}_{M}(\mathrm{j}) & =\left(\mathrm{m}_{\mathrm{ij}}\right), \forall \mathrm{i} \in\{0,1, \ldots, \mathrm{~m}-1\}
\end{aligned}
$$

are the $i^{\text {th }}$ row and the $j^{\text {th }}$ column of matrix M , respectively. Each value of $x \in\left\{2^{i} \mid 0 \leq i \leq n-1\right\}$ is equivalent to a vector with 1 at the $i^{\text {th }}$ row

$$
2^{0}=\left(\begin{array}{c}
1 \\
0 \\
\vdots \\
0
\end{array}\right) \quad 2^{1}=\left(\begin{array}{c}
0 \\
1 \\
\vdots \\
0
\end{array}\right) \quad \cdots \quad 2^{\mathrm{n}-1}=\left(\begin{array}{c}
0 \\
0 \\
\vdots \\
1
\end{array}\right)
$$

Clearly, every column, except the $\mathrm{i}^{\text {th }}$, becomes zero when multiplying the matrix $M$ by $x$. Hence, each column of the matrix $M$ can be obtained using equation

$$
\operatorname{cols}_{M}(\mathrm{i})=\mathrm{L}\left(2^{\mathrm{i}}\right), \quad \mathrm{i} \in\{0,1, \ldots, \mathrm{n}-1\} .
$$

For obtaining all columns of $M$ it is necessary to compute n values of $\mathrm{L}\left(2^{\mathrm{i}}\right), 0 \leq \mathrm{i} \leq \mathrm{n}-1$. Consequently the complexity of transformation is $\mathrm{O}(\mathrm{n})$.

Proposition 2. Any $n \times n$ matrix $M$ can be converted to a linear function $L: F_{2}^{\mathrm{n}} \mapsto \mathscr{F}_{2}^{\mathrm{n}}$ with the complexity $\mathrm{O}\left(\mathrm{n}^{3}\right)$ filed operations.

Proof. Any linear transformation has the form

$$
\begin{equation*}
M \cdot x=L(x)=\sum_{i=0}^{n-1} \delta_{i} x^{2^{i}} \tag{3}
\end{equation*}
$$

where $\square$ in $F_{2^{n}}$. Then using (3) for every $\mathrm{x}=2^{\mathrm{i}}, 0 \leq \mathrm{i} \leq \mathrm{n}-1$, the equation could be rewritten as

$$
\begin{gathered}
\left(\begin{array}{c}
\operatorname{cols}_{M}(0) \\
\operatorname{cols}_{M}(1) \\
\vdots \\
\operatorname{cols}_{M}(n-1)
\end{array}\right)= \\
=\left(\begin{array}{cccc}
\left(2^{0}\right)^{2^{0}} & \left(2^{0}\right)^{2^{1}} & \cdots & \left(2^{0}\right)^{2^{n-1}} \\
\left(2^{1}\right)^{2^{0}} & \left(2^{1}\right)^{2^{1}} & \cdots & \left(2^{1}\right)^{2^{n-1}} \\
\vdots & \vdots & \ddots & \vdots \\
\left(2^{n-1}\right)^{2^{0}} & \left(2^{n-1}\right)^{2^{1}} & \cdots & \left(2^{n-1}\right)^{2^{n-1}}
\end{array}\right) \times\left(\begin{array}{c}
\delta_{0} \\
\delta_{1} \\
\vdots \\
\delta_{n-1}
\end{array}\right)
\end{gathered}
$$

The complexity of acquiring vector $\left\{\delta_{0}, \delta_{1}, \ldots, \delta_{n-1}\right\}$ is corresponding to obtaining the inverse matrix and equals $\mathrm{O}\left(\mathrm{n}^{3}\right)$ field operations.

In practice, the Lagrange interpolation method [14] works faster for $\mathrm{n} \leq 6$ and much slower otherwise.

Proposition 3. Let $\quad \mathrm{F}, \mathrm{G}: F_{2}^{\mathrm{n}} \mapsto F_{2}^{\mathrm{m}} \quad$ and $\mathrm{G}^{\prime}(\mathrm{x})=\mathrm{G}(\mathrm{x}) \oplus \mathrm{G}(0)$. Then the complexity of checking $F$ and $G$ for REA-equivalence of type $I$ equals
$-\mathrm{O}\left(2^{\mathrm{n}+1}\right)$ in case when for any $\mathrm{i} \in\{0, \ldots, \mathrm{~m}-1\}$ there exists $\mathrm{x} \in \mathcal{F}_{2}^{\mathrm{n}}$ such that $\mathrm{G}^{\prime}(\mathrm{x})=2^{\mathrm{i}}$;
$-\mathrm{O}\left(\mathrm{m} \cdot 2^{2 \mathrm{n}}\right)$ in case G is arbitrary.
Proof. Let $F^{\prime}(x)=F(x) \oplus F(0)$. Then REAequivalent of type $I$

$$
\mathrm{F}^{\prime}(\mathrm{x}) \oplus \mathrm{F}(0)=\mathrm{M}_{1} \cdot \mathrm{G}^{\prime}(\mathrm{x}) \oplus \mathrm{M}_{1} \cdot \mathrm{G}(0) \oplus \mathrm{V}_{1}
$$

can be rewritten in the following form

$$
\left\{\begin{array}{l}
\mathrm{F}(0)=\mathrm{M}_{1} \cdot \mathrm{G}(0) \oplus \mathrm{V}_{1}  \tag{4}\\
\mathrm{~F}^{\prime}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}^{\prime}(\mathrm{x})
\end{array}\right.
$$

In case of $G(0)=0, V_{1}$ equals $F(0)$, but in general it's necessary first to find $\mathrm{M}_{1}$ from equation $F^{\prime}(x)=M_{1} \cdot G^{\prime}(x)$. If the set $\left\{2^{i} \mid 0 \leq i \leq m-1\right\}$ is the
subset of the image set of $\mathrm{G}^{\prime}$, then the problem of finding $\mathrm{m} \times \mathrm{m}$ matrix $\mathrm{M}_{1}$ is equivalent to the problem of converting linear function to matrix form with additional testing for all x in $F_{2}^{\mathrm{n}}$. It is possible to find $M_{1}$ with the complexity $O(m)$ as was shown in Proposition 1. The complexity of finding the pre-images of $\mathrm{G}^{\prime}$ of elements $2^{\mathrm{i}}, \forall \mathrm{i} \in\{0, \ldots, \mathrm{~m}-1\}$ equals $\mathrm{O}\left(2^{\mathrm{n}}\right)$ as well as the complexity of checking $F^{\prime}(x)=M_{1} \cdot G^{\prime}(x)$ for given $M_{1}$. In cryptography, in most cases $2^{\mathrm{n}} \gg \mathrm{m}$, so the complexity $\mathrm{O}(\mathrm{m})$ can be neglected. Therefore, the total complexity of verification for equivalence of $F$ and $G$ equals $\mathrm{O}\left(2^{\mathrm{n}}+2^{\mathrm{n}}+\mathrm{m}\right) \approx \mathrm{O}\left(2^{\mathrm{n}+1}\right)$.

Let now $G$ be arbitrary and $F^{\prime}(x)_{i}$ be the $i^{\text {th }}$ bit of $F^{\prime}(x)$. Denote $\operatorname{img}\left(G^{\prime}\right)$ the image set of $G^{\prime}$ and $\mathrm{u}_{\mathrm{G}^{\prime}}=\left|\operatorname{img}\left(\mathrm{G}^{\prime}\right)\right|$ the number of elements in $\operatorname{img}\left(\mathrm{G}^{\prime}\right)$. Let also $\mathrm{N}_{\mathrm{G}}$ be any subset of $\mathcal{F}_{2}^{\mathrm{n}}$ such that $\left|N_{G^{\prime}}\right|=\mathrm{u}_{\mathrm{G}^{\prime}}$ and $\left|\left\{\mathrm{G}^{\prime}(\mathrm{a}) \mid \mathrm{a} \in \mathrm{N}_{\mathrm{G}^{\prime}}\right\}\right|=\mathrm{u}_{\mathrm{G}^{\prime}}$.

Then to find $M_{1}$ it is necessary to solve a system below for all $\mathrm{i} \in\{0, \ldots, \mathrm{~m}-1\}$

$$
\begin{aligned}
\mathrm{F}^{\prime}\left(\mathrm{x}_{\mathrm{j}}\right)_{\mathrm{i}} & =\operatorname{rows}_{\mathrm{M}_{1}}(\mathrm{i}) \cdot \mathrm{G}^{\prime}\left(\mathrm{x}_{\mathrm{j}}\right), \forall \mathrm{x}_{\mathrm{j}} \in \mathrm{~N}_{\mathrm{G}^{\prime}}, 0 \leq \mathrm{j} \leq \mathrm{u}_{\mathrm{G}^{\prime}}-1 \Leftrightarrow \\
& \Leftrightarrow\left\{\begin{array}{l}
\mathrm{F}^{\prime}\left(\mathrm{x}_{0}\right)_{\mathrm{i}}=\operatorname{rows}_{\mathrm{M}_{1}}(\mathrm{i}) \cdot \mathrm{G}^{\prime}\left(\mathrm{x}_{0}\right) ; \\
\mathrm{F}^{\prime}\left(\mathrm{x}_{1}\right)_{\mathrm{i}}=\operatorname{rows}_{\mathrm{M}_{1}}(\mathrm{i}) \cdot \mathrm{G}^{\prime}\left(\mathrm{x}_{1}\right) ; \\
\ldots \\
\mathrm{F}^{\prime}\left(\mathrm{x}_{\left.\mathrm{u}_{\mathrm{G}^{\prime}-1}\right)_{\mathrm{i}}=\operatorname{rows}_{\mathrm{M}_{1}}(\mathrm{i}) \cdot \mathrm{G}^{\prime}\left(\mathrm{x}_{\mathrm{u}_{\mathrm{G}^{\prime}-1}}\right)}\right.
\end{array}\right.
\end{aligned}
$$

For every i in $\{0, \ldots, m-1\}$, the complexity of solving the system highly depends on $\mathrm{u}_{\mathrm{G}^{\prime}}$ and m and equals $\mathrm{O}\left(\max \left\{\mathrm{u}_{\mathrm{G}^{\prime}}, \mathrm{m}\right\}^{2}\right)$ according to (2). Then the total complexity of obtaining $\mathrm{M}_{1}$ for all m bits is $\mathrm{O}\left(\mathrm{m} \cdot \max \left\{\mathrm{u}_{\mathrm{G}^{\prime}}, \mathrm{m}\right\}^{2}\right)$. If value $\mathrm{u}_{\mathrm{G}^{\prime}} \approx 2^{\mathrm{n}}$, then $\mathrm{O}\left(\mathrm{m} \cdot 2^{2 \mathrm{n}}\right)$.

Remark 1. If it is known in advance that functions $F$ and $G$ in Proposition 3 are REA-equivalent of type I, then the complexity of verification $\mathrm{F}^{\prime}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}^{\prime}(\mathrm{x})$ can be ignored and the total complexity for the case $\left\{2^{\mathrm{i}} \mid 0 \leq \mathrm{i} \leq \mathrm{m}-1\right\} \subset \operatorname{img}\left(\mathrm{G}^{\prime}\right)$ becomes $\mathrm{O}\left(2^{\mathrm{n}}\right)$.

Proposition 4. Let $G$ be a permutation and $\mathrm{F}, \mathrm{G}: \mathscr{F}_{2}^{\mathrm{n}} \mapsto \mathscr{F}_{2}^{\mathrm{n}}$. Then the complexity of checking F and $G$ for REA-equivalence of type II is $\mathrm{O}\left(\mathrm{n}^{2}\right)$.

Proof. Denote $\mathrm{H}(\mathrm{x})=\mathrm{G}^{-1}(\mathrm{~F}(\mathrm{x}))$. Then the equation $\mathrm{F}(\mathrm{x})=\mathrm{G}\left(\mathrm{M}_{2} \cdot \mathrm{x} \oplus \mathrm{V}_{2}\right)$ takes the form

$$
H(x)=M_{2} \cdot x \oplus V_{2}
$$

Obviously for satisfying REA-equivalence H must be linear and invertible. Arbitrary linear function from
$F_{2}^{\mathrm{n}}$ to $F_{2}^{\mathrm{m}}$ has the form (3) thence consists at most of n monomials. Suppose $\psi(\mathrm{n})$ the complexity of obtaining binary Hamming weight of the monomials exponents in H. Consequently the complexity for checking linearity of H with equals $\mathrm{O}(\mathrm{n} \cdot \psi(\mathrm{n}))$. For the most of modern processors including Intel the value $\psi(\mathrm{n})$ is equal to O (1) [15]. Taking $\mathrm{x}=0$ we obtain $\mathrm{V}_{2}=\mathrm{H}(0)$ and the equivalence can be represented as $H^{\prime}(x)=M_{2} \cdot x$, where $\quad H^{\prime}(x)=H(x) \oplus H(0)$. For satisfying REAequivalence conditions the matrix $\mathrm{M}_{2}$ must be nonsingular. Therefore, the total complexity is equal to the sum of checking linearity of $\mathrm{H}(\mathrm{O}(\mathrm{n}))$, obtaining matrix $\mathrm{M}_{2}(\mathrm{O}(\mathrm{n}))$ and checking it on invertibility $\left(\mathrm{O}\left(\mathrm{n}^{2}\right)\right)$ and approximately equals $\mathrm{O}\left(\mathrm{n}^{2}\right) . \square$

Proposition 5. Let $\mathrm{F}, \mathrm{G}: F_{2}^{\mathrm{n}} \mapsto \mathcal{F}_{2}^{\mathrm{m}}$. Then the complexity of checking F and G for REA-equivalence of type III equals $\mathrm{O}(\mathrm{n})$.

Proof. Denote $\mathrm{H}(\mathrm{x})=\mathrm{F}(\mathrm{x}) \oplus \mathrm{G}(\mathrm{x})$, then REAequivalence

$$
\mathrm{F}(\mathrm{x})=\mathrm{G}(\mathrm{x}) \oplus \mathrm{M}_{3} \cdot \mathrm{x} \oplus \mathrm{~V}_{1}
$$

takes the form

$$
H(x)=M_{3} \cdot x \oplus V_{1}
$$

The situation is the same as in Proposition 4, but with arbitrary $\mathrm{m} \times \mathrm{n}$ matrix. Thus the complexity of obtaining $\mathrm{M}_{3}$ and $\mathrm{V}_{1}$ equals $\mathrm{O}(\mathrm{n})$.

Every vectorial Boolean function admits the form

$$
\begin{equation*}
\mathrm{H}(\mathrm{x})=\mathrm{H}^{\prime}(\mathrm{x}) \oplus \mathrm{L}_{\mathrm{H}}(\mathrm{x}) \oplus \mathrm{H}(0) \tag{5}
\end{equation*}
$$

where $L_{H}$ is a linear function and $H^{\prime}$ has terms of algebraic degree at least 2.

Proposition 6. Let $\mathrm{G}^{\prime}$ be defined by (5) and $\mathrm{F}, \mathrm{G}: F_{2}^{\mathrm{n}} \mapsto \mathscr{F}_{2}^{\mathrm{m}}$. Then the complexity of checking F and $G$ for REA-equivalence of type IV equals
$-\mathrm{O}\left(2^{\mathrm{n}+1}\right)$ in case $\left\{2^{\mathrm{i}} \mid 0 \leq \mathrm{i} \leq \mathrm{m}-1\right\} \subset \operatorname{img}\left(\mathrm{G}^{\prime}\right)$,
$-\mathrm{O}\left(\mathrm{m} \cdot 2^{2 \mathrm{n}}\right)$ in case G is arbitrary.
Proof. Using (5) REA-equivalence of type IV can be rewritten as
$\mathrm{F}^{\prime}(\mathrm{x}) \oplus \mathrm{L}_{\mathrm{F}}(\mathrm{x}) \oplus \mathrm{F}(0)=\mathrm{M}_{1} \cdot \mathrm{G}^{\prime}(\mathrm{x}) \oplus \mathrm{M}_{1} \cdot \mathrm{~L}_{\mathrm{G}}(\mathrm{x}) \oplus$
$\oplus M_{3} \cdot x \oplus M_{1} \cdot G(0) \oplus V_{1}$
and gives the system of equations

$$
\left\{\begin{array}{l}
\mathrm{F}^{\prime}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}^{\prime}(\mathrm{x}) \\
\mathrm{L}_{\mathrm{F}}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{~L}_{\mathrm{G}}(\mathrm{x}) \oplus \mathrm{M}_{3} \cdot \mathrm{x} \\
\mathrm{~F}(0)=\mathrm{M}_{1} \cdot \mathrm{G}(0) \oplus \mathrm{V}_{1}
\end{array}\right.
$$

It's easy to see that for a given $\mathrm{M}_{1}$ one can easily compute $\mathrm{M}_{3}$ and $\mathrm{V}_{1}$ from the second and the third equations of the system. The first equation of the system leads to the two different cases for the function $G^{\prime}$ considered in Proposition 3. Hence, according to Proposition 2, the total complexity for finding $\mathrm{G}^{\prime}$
equals $\mathrm{O}\left(2^{\mathrm{n}+1}\right)$ and $\mathrm{O}\left(\mathrm{m} \cdot 2^{2 \mathrm{n}}\right)$, respectively. It should be noted that the complexity of finding the matrix $\mathrm{M}_{3}$ is not taken into account since $2^{\mathrm{n}+1} \gg \mathrm{n}$.

If we add one of $\mathrm{V}_{1}, \mathrm{~V}_{2}$ values to REAequivalence, then the complexity will increase in $2^{\mathrm{m}}$ or $2^{\mathrm{n}}$ times respectively. REA-equivalance with $\mathrm{V}_{1}, \mathrm{~V}_{2}$ and corresponding complexities are shown in Table 1. It should be mentioned that types I and III of REAequivalence are particular cases of type IV. But taking into account different restrictions for the function $G$ it is necessary to check all these types of EA-equivalence.

An algorithm for the type IV of REA-equivalence in case $\left\{2^{\mathrm{i}} \mid 0 \leq \mathrm{i} \leq \mathrm{m}-1\right\} \subset \operatorname{img}\left(\mathrm{G}^{\prime}\right)$ is given below.

```
Algorithm 1 Checking Functions for REA-equivalence of Type IV
    Input: F
    Output: True if F is EA-equivalent to G
    for }\mp@subsup{V}{2}{}=0\mathrm{ to 2}\mp@subsup{2}{}{n}\mathrm{ do
        H'(x)\leftarrowG''(x\oplus\mp@subsup{V}{2}{});
        LH}(x)\leftarrow\mp@subsup{L}{G}{}(x\oplus\mp@subsup{V}{2}{})
        H(0)\leftarrowG(V V );
        for i=0 to m-1 do
            x}\leftarrow\mp@subsup{2}{}{i}
            find(2}\mp@subsup{2}{}{i}==G(y))
            SetColumn( }\mp@subsup{M}{1}{},i,H(y))
        end for
        V1}\leftarrow\mp@subsup{M}{1}{}\cdotH(0)\oplusF(0)
        for }i=0\mathrm{ to }n-1\mathrm{ do
            x}\leftarrow\mp@subsup{2}{}{i}
            SetColumn ( M M ,i,L_F (x)\oplus M
        end for
        for i=0 to 2}\mp@subsup{2}{}{n}-1 d
            if F
                goto next V2;
            end if
        end for
        return True
    end for
    return False
```

## Conclusions

The present paper studies complexities of checking functions for special cases of EA-equivalence and it is shown that for some of this cases the complexity of checking takes polynomial time. Obtained results give a practical method for checking functions on equivalence. The best result is with the complexity $\mathrm{O}\left(2^{2 \mathrm{n}+1}\right)$ for checking REA-equivalence of the form $F(x)=M_{1} \cdot G\left(x \oplus V_{2}\right) \oplus M_{3} \cdot x \oplus V_{1} \quad$ under $\quad$ some condition on G .

# ПЕРЕВІРКА ВЕКТОРНИХ БУЛЕВИХ ФУНКЦІЙ НА ОБМЕЖЕНУ РОЗШИРЕНО АФІННУ ЕКВІВАЛЕНТНІСТЬ 

Л. Будагян, О. Казимиров

У статті представлені алгоритми для вирішення проблеми обмеженої расширено афінної еквівалентності (ОР $A$ еквівалентності) у разі довільної т-мірної векторної булевої функиїї від п змінних. Кращий з отриманих алгоритмів має складність $\mathrm{O}\left(2^{2 \mathrm{n}+1}\right)$ для ОРА-еквівалентності $\mathrm{F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}\left(\mathrm{x} \oplus \mathrm{V}_{2}\right) \oplus \mathrm{M}_{3} \cdot \mathrm{x} \oplus \mathrm{V}_{1}$. Складності розроблених методів порівнюються з запропонованими раніше Бірюковим та ін. алгоритмами для вирішення проблем лінійних та афінних еквівалентностей.

Ключові слова: РА-еквівалентність, матричне уявлення, S-блок, векторні булеві функиії.

## ПРОВЕРКА ВЕКТОРНЫХ БУЛЕВЫХ ФУНКЦИЙ

 НА ОГРАНИЧЕННУЮ РАСШИРЕННО АФИННУЮ ЭКВИВАЛЕНТНОСТЬ
## Л. Будагян, А. Казимиров

В статье представлены алгоритмь для решения проблемы ограниченной расширенно аффинной эквивалентности (ОРА-эквивалентности) в случае произвольной т-мерной векторной булевой функиии от $n$ переменных. Лучший из предложенных алгоритмов имеет сложность $\mathrm{O}\left(2^{2 \mathrm{n}+1}\right)$ для ОРА-эквивалентности $\mathrm{F}(\mathrm{x})=\mathrm{M}_{1} \cdot \mathrm{G}\left(\mathrm{x} \oplus \mathrm{V}_{2}\right) \oplus \mathrm{M}_{3} \cdot \mathrm{x} \oplus \mathrm{V}_{1}$. Сложности разработанных методов сравниваются с предложенными ранее Бирюковым и др. алгоритмами для решения проблем линейных и аффинных эквивалентностеи.

Ключевые слова: РА-эквивалентность, матричное представление, $S$-блок, векторные булевы функиии.
